Abstract
Purpose: This study examines the impact of foreign direct investment (FDI) on the gross domestic product (GDP) growth rate in Nigeria from 1990 to 2021.
Research methodology: This study employed time-series data from the World Bank’s World Development Indicator Database to ensure data homogeneity. The data were assessed for stationarity using the ADF unit root test. All the data were stationary after the first difference. The hypothesis was tested using ordinary least squares (OLS) with BLUE properties.
Results: The study finds a significant positive effect of foreign direct investment net inflow on GDPGR (p<.05). The control variables DEGO (p=0.3299) and INFL (p=0.3321) showed positive coefficients but were non-significant.
Limitations: The study used only data from the Nigerian context, from 1990 to 2021, which affects the generalizability of the study findings to other countries in SSA, and a limited number of control variables, such as DEGO and INFL.
Contribution: This study contributes to the literature on FDI’s impact on the economic growth of African nations. The research findings have critical policy implications for governments aiming to achieve sustainable economic growth.
Practical Implications: This study has policy implications for developmental governance in Nigeria and SSA countries.
Novelty: This study deviates from prior studies that agree that illicit financial flows in the form of FDI outflows negatively affect growth and focus on FDI net inflows’ beneficial impacts on the Nigerian economy.
Keywords: Foreign Direct Investment, GDP Growth Rate, Degree of Economic Openness, Inflation

1. Introduction
Foreign Direct Investment (FDI) is a direct investment in the production or business of a company or country by a foreign firm or the effective participation in management that can result in the inflow of new equity capital (Kunle, Olowe, & Oluwafolakemi, 2014; Nwankwo, Ademola, & Kehinde, 2013). Foreign direct investment (FDI) is a significant source of funding for developing nations (Rao, Sethi, Dash, & Bhujabal, 2023). To encourage economic growth and national welfare, wealthier countries primarily provide developing countries with official development assistance (ODA) (OECD, 2023). FDI is usually transmitted by Transnational or Multinational Corporations (T/MNCs) and plays a role in a nation’s development through channels such as capital accumulation, knowledge transfer, and managerial expertise (Divamett & Mutambla, 2014; L. Erdal & Göcer, 2015). These spillover effects have been identified as a major source of technological development in developing countries (Ivarsson...
According to Bassey, Amobi, and Okorie (2022), most governments, especially in Sub-Saharan Africa (SSA), actively sway MNCs to locate their overseas investments through a variety of means. FDI is regarded as one of the major channels of technology diffusion across borders, which could translate into technological development in the host country (Bodman & Le, 2013; Osano & Koine, 2016). Such transmission can occur in several ways, including the import of high-technology products (Kwark & Shvn, 2006), foreign technology payments, direct adoption of foreign technology (Soete & Patel, 1985), and acquisition of human capital (Le, 2008; Le & Bodman, 2011; Park, 2004). Since the 80s FDI has become dominant, and is expected to become even more dominant in the foreseeable future. Factors accounting for this shift include the ongoing global trend of FDI liberalization, large-scale abolition of international trade barriers, increased globalization, and the growing need for technological competitiveness to survive and grow economically (Kadah, 2003).

GDP growth rate is a measure of the growth or expansion of an economy over a specific period. It is usually expressed as a percentage increase in gross domestic product (GDP) from one year to another (Encinas-Ferrer & Villegas-Zermeño, 2015). A positive growth rate indicates economic expansion, whereas a negative growth rate suggests a contraction in the economy. GDP growth rate is an important indicator that helps economists and policymakers understand the overall health and performance of an economy. Following neoliberal principles, developing nations have prioritized FDI since the late 80s and particularly during the 90s. Programs and policies were developed within countries with the intention of luring FDIs from developed countries to emerging countries. This was done under the assumption that the flow of investment from developed countries has a necessary consequence on economic growth (Encinas-Ferrer & Villegas-Zermeño, 2015). Thus, many developing nations worldwide are attempting to use FDI to fuel economic growth, measured in terms of GDP (gross domestic product) (Talwar & Srivastava, 2018). It is widely accepted that nations should permit FDI or foreign direct investment, to support initiatives and plans that boost growth. Many nations use highly lenient FDI-related policies.

Nigeria is a typical developing nation, with the industrial sector (comprising manufacturing, mining, and utilities) contributing an insignificant proportion of the economic activity and GDP (Chete, Adeoti, Adevinka, & Ogundele, 2014). Given the importance of FDI, the Nigerian government has put in place various incentives, policies, and regulatory measures to promote the inflow of FDI to the country (Kunle et al., 2014). Studies have mainly focused on the impact of FDI on economic growth (Adigwe, Ezeagba, & Udeh, 2015; Kunle et al., 2014; Olokoyo, 2012; Umoh, Jacob, & Chuku, 2012). However, growth results either from the accumulation of factors of production or from improvements in technology or both (Lemma, Kitaw, & Gatew, 2014). Studies have shown support for FDI, which is needed to bridge the gap that exists in Africa in general and Nigeria in particular (Adigwe et al., 2015; Kunle et al., 2014; Olokoyo, 2012; Umoh et al., 2012). This study examines the impact of FDI on the GDP growth rate (GDPGR) in Nigeria. The article’s conclusions provide a summary of the findings. Our findings from alternative empirical specifications, such as OLS and DOLS, show that FDI positively correlates with GDPGR, which is also consistent with the variable DEGO on GDPGR.

2. Literature Review
2.1. Conceptual Review
2.1.1. Foreign Direct Investment (FDI)
FDI is “a form of inter-firm cooperation that involves a significant equity stake in or effective management control of foreign enterprise” (L. Erdal & Göçer, 2015). FDI is a direct investment in production or business in a country by an individual or company in another country, either by buying a company in the target country or expanding the operations of an existing business in that country (Kunle et al., 2014). It can be analyzed in terms of the inflow of new equity capital (change in foreign share capital), re-invested earnings (unremitted profit), trade and supplier’s credit, net inflow of borrowing,
and other obligations from the parent company or its affiliates (Nwankwo et al., 2013). FDI refers to the long-term participation of one country in another country, usually in the form of participation in management, joint ventures, transfer of technology, and expertise (K. H. Zhang, 2001).

The International Monetary Fund (IMF) (IMF, 1993, 2001) and the Organisation for Economic Co-operation and Development (OECD) (OECD, 1996) defined FDI as a long-term investment by foreign direct investors in an enterprise resident in an economy other than that in which the foreign direct investor is based. Rutherford (1992) defines FDI as business investment in another country, which often takes the form of setting up local production facilities (through greenfield) or purchasing an existing business through mergers and acquisitions (M&As). Foreign direct investments are distinguished from portfolio investments, in which investors merely purchase equities of foreign-based companies. The key feature of foreign direct investment is that it is an investment made to establish either effective control of, or at least substantial influence over, the decision making of a foreign business entity.

The FDI relationship consists of a parent enterprise and foreign affiliate that together form a transnational corporation (TNC). To qualify as FDI, the investment must afford the parent enterprise control over its foreign affiliate. For an investment to be regarded as FDI, the parent firm needs to have at least 10% of its foreign affiliates’ ordinary shares, but the investing firm may also qualify for FDI if it owns voting power in a business enterprise operating in a foreign country (Sharma & Gani, 2004). UNCTAD defines control in this case as owning 10 per cent or more of the ordinary shares or voting power of an incorporated firm or its equivalent for an unincorporated firm. Other ways in which foreign investors may acquire control include subcontracting, management contracts, turnkey arrangements, franchising, leasing, licensing, and production sharing.

FDI influences production, employment, income, prices, exports, imports, economic growth, the balance of payments, and general welfare in the host country (F. Erdal & Tatoglu, 2002; Olokoyo, 2012). There are two types of FDI, inward foreign direct investment and outward foreign direct investment, resulting in a net FDI inflow (positive or negative) (Damooei & Tavakoli, 2006). The three major motives for inward FDI apart from locating production in a foreign country are resource seeking, market-seeking, and efficiency seeking (Dunning, 1993):

1. In the first category, MNEs aim to acquire particular types of resources that are not available at home (such as natural resources or raw materials) or that are available at a lower cost (such as unskilled labor offered at a cheaper price with respect to the home country) (Divamett & Mutambla, 2014).
2. In the second category, MNEs invest in foreign countries to exploit the possibilities granted by markets with greater dimensions. Other reasons that push MNEs to choose market seeking (besides searching and exploiting new markets) include the following suppliers or customers that have built foreign production facilities, adapt goods to local needs or tastes, and save the cost of serving a market from a distance. Recently, it has become important to have a physical presence in the market to discourage potential competitors from occupying the market (Divamett & Mutambla, 2014).
3. In the third category, an MNE intends to take advantage of different factor endowments, cultures, institutional arrangements, economic systems and policies, and market structures that are amenable to efficient production (Divamett & Mutambla, 2014).

2.1.2. Channels of FDI Spillovers

FDI builds local technological capabilities through various channels. These channels are vertical and horizontal linkages. Through vertical linkages, on the one hand, FDI builds local technological capabilities through backward and forward linkages. Backward linkages are relationships with suppliers of parts, components, materials, and services. Forward linkages refer to relationships with buyers—either consumers or other firms—using MNEs’ intermediate products in their processes. Downstream firms can use higher-quality and/or lower-priced intermediate goods in their processes, which then benefits consumers through cheaper final products. On the other hand, through horizontal linkages, FDI builds local technological capabilities through demonstration, competition, and labor migration. The
demonstration effect occurs when local companies see the superior technology of the MNE and therefore update their own (Saggi, 2002) or imitate new technologies used by MNEs.

MNEs, in turn, upgrade their technologies as a result of competition. The greater the competition, the more MNEs will have to bring in new technology to retain their competitive advantage, leading to greater potential spillovers (Wang & Blomström, 1992). However, if local firms are not sufficiently developed to compete, the superior technology of MNEs can crowd them out. Spillovers can also occur through the exchange of human capital, where technology is transferred through workers formerly employed by MNEs moving to local firms or setting up their firms.

There are three main channels through which FDI leads to economic growth. The first is the release it affords from the binding constraint of domestic savings. In this case, foreign direct investment augments domestic savings through capital accumulation. Second, FDI is the main conduit through which technology spillovers lead to an increase in factor productivity and efficiency in resource utilization, which leads to growth. Third, FDI leads to an increase in exports because of increased capacity and competitiveness in domestic production. This linkage is often said to depend on another factor, called “absorptive capacity,” which includes the level of human capital development, type of trade regimes, and degree of openness (Ajayi, 2006; Borensztein, De Gregorio, & Lee, 1998).

Todaro (2000) argues that FDI in services affects the host country’s competitiveness by raising the productivity of capital and enabling the host country to attract new capital on favorable terms. Swenson (2004) contends that FDI improves competitiveness through technology transfer and the effects of myriad externalities. According to Kunle et al. (2014), FDI version and technology chnologilo and Edevelo.,N and evNdevelop.,ing economies such as Nigeria. This view is supported by Otepola (2002), who states that FDI has emerged as the most important source of external resource flows to developing countries. Lemma et al. (2014) observe that technological inflow through FDI is an important conduit for promoting local industries to upgrade and be competitive in the marketplace. FDI is an important source of non-debt inflows and is increasingly sought as a means of attaining competitive efficiency by creating a meaningful network of global interconnections (Olokoyo, 2012).

The factors that affect FDI include inflation, the exchange rate, uncertainty, credibility, government expenditure, and institutional and political factors. Other factors include domestic interest rates, debt services, credit ratings, and political stability (Ekpo, 1997). The FDI literature identifies and classifies the motives that encourage companies to invest overseas into four (UNCTAD, 2008). These are:
1) Market-seeking motives highlight access to new markets that are attractive because of their present size and identified potential for expansion.
2) Efficiency-seeking motives aim to take advantage of cost-efficient production methods. This is approximated by the cost and productivity of capital, labor, infrastructure, and the administrative cost of doing business.
3) The natural resource-seeking motive seeks to tap into the natural resource endowments in the locations being considered against others.
4) Strategic asset-seeking motives are oriented towards man-made assets, as embodied in the quality of the workforce, brand names, and market shares.

126
Demonstration and competition effects. Higher quality of foreign products should stimulate improvements in the quality of domestic firms.

Nigeria is immensely blessed with natural resources such as vast agricultural land suitable for the cultivation of crops, an estimated 124 trillion cubic feet of proven natural gas reserves, huge deposits of crude oil and gas, and a large expanse of solid mineral deposits that have hardly been exploited. However, corruption, mismanagement, and inefficiencies have resulted in a country with a GDP of approximately US$212b, and an annual growth rate of 5.3%. The GDP amounts to about 41% of that of the sub-region, while the GDP per capita is $300. Globally, Nigeria is among the 20 poorest countries and has a very high debt profile (Group, 2012). The level of FDI attracted by Nigeria is mediocre compared to the resource base and potential need (Asiedu & Lien, 2004), which qualifies it as a major recipient of FDI in Africa (Olokoyo, 2012). Attempts to attract FDI into the Nigerian economy have been based on the need to maximize the potential benefits derived from them and to minimize the negative effects of their operations on the country (Olokoyo, 2012).

In 1995, the government enacted two major laws to encourage FDI inflow. The two laws are the Nigerian Investment Promotion Commission (NIPC) Act 16 and Foreign Exchange (Monitoring and Miscellaneous Provision) Act 17 (Olokoyo, 2012). The NIPC was established to address the multiplicity of government agencies that investors confront when they come to Nigeria. Thus, the commission assists investors in going through the formerly cumbersome process of pre-investment registration within two weeks. The commission guarantees the protection of foreign interests in Nigeria against expropriation, administers appropriate incentive packages available to investors, guarantees the transferability of profits and other funds by investors, identifies difficulties and problems encountered by investors and proffer solutions, and assists them. The NIPC provides up-to-date information on investment opportunities available in the country, links foreign investors with local partners, provides information on available incentives for investment, issues business permits to foreign investors, coordinates the issuance of expatriate quotas, negotiates in consultation with appropriate government agencies, provides specific incentive packages for investors, enters directly into a bilateral agreement with investors for the purpose of investment promotion, and identifies the specific project and invites interested investors to partake in them (Olokoyo, 2012).

2.1.3. GDP
Gross Domestic Product (GDP) is a monetary measure of the market value of all final goods and services produced by a country in a specific period (OECD, 2023). GDP is most often used by the government of a single country to measure its economic health. GDP can be calculated in three ways: using expenditures, production, or income, and can be adjusted for inflation and population to provide deeper insights. Real GDP accounts for the effects of inflation, while nominal GDP does not. The GDP calculates the total cost of all final products and services purchased in a nation (less imports) within a given period. We also calculate the income generated from these purchases. The GDP is the most significant indicator of economic activity.

2.1.4. FDI and GDP nexus
FDI is the dominant international technology transfer channel. Although non-FDI forms of international technology transfer have been growing since the 1960s, FDI forms have become dominant since the 1980s, and are expected to become even more dominant in the foreseeable future. Factors accounting for this shift include, among others, the ongoing global trend of FDI liberalization, large-scale abolition of international trade barriers, increased globalization of economic activities, and the growing need for technological competitiveness to survive and grow economically. FDI can provide firms with new markets and marketing channels, cheaper production facilities, and access to new technology, products, skills, and financing. For a host country or a foreign firm that receives the investment, it can provide a source of new technologies, capital, processes, products, organizational technologies, and management skills, and as such, can provide a strong impetus to economic development.
A different researcher, Alemu Alemu (Alemu, 2017) used a dynamic GMM model to analyze the effects of foreign aid and FDI on economic growth in middle- and low-income African countries. The results showed that middle-income countries tended to experience more FDI impacts than low-income countries did. Another study (Koroci, 2018) that focused on Albania found a significant positive correlation between FDI inflows and GDP from 1995 to 2012. FDI and economic growth were found to be cointegrated at the panel level in a study by Agrawal (2015), who examined the relationship between them over the 1989-2012 time period in five BRICS economies. This finding suggests a long-term equilibrium relationship between them.

2.2. Theoretical Framework
This study is based on the new trade theory (NTT) proposed by Samuelson (1939) and Stolper and Samuelson (1941). Through the lens of economies of scale, imperfect competition, and product differentiation, NTT examines the patterns and determinants of international commerce. This argument, put forth by economists Paul Krugman and Elhanan Helpman in the 1980s, contests the conventional wisdom that trade is driven only by comparative advantage. According to this theory, new or differentiated goods, markets separated into sections, changes in technology, and economies of scale have become the most important issues in obtaining more competitive power in the global market (Porter, 1998). Today, the new trade theory proposed by Krugman (1979) and Dixit and Stiglitz (1977) and strengthened by Melitz (2003) argues that international trade is no longer carried out by the state, but by MNCs producing new high technology that makes them more competitive in the global market (Bakkalci, 2013). In other words, developing countries, even if they cannot produce different high-tech products, can import them via FDI (L. Erdal & Göçer, 2015). Nigeria is a country with rich and abundant natural resources. Although it is monolithic in nature, its growth and development are poor compared to those of its abundant natural resources. Therefore, growth can be achieved by importing high-technology products and managerial expertise in the form of FDI.

2.3. Empirical Review
Using a sample of countries in South Asia and Southeast Asia, Rao et al. (2023) examined how foreign aid, FDI, and economic growth interacted between 1980 and 2016. The multiple regression analysis showed according to the results of alternative empirical estimations, that FA is negatively associated with FDI and economic growth whereas FDI is positively associated with the economic growth proxy.

Shinwari, Zakeria, Usman, and Sadiq (2023) explored Afghanistan’s FDI and economic growth nexus using data that spanned from 2001 to 2020. The data were analyzed using the autoregressive distributed lag (ARDL) technique and showed that FDI positively affected economic growth. Magazzino and Mele (2022) investigate the effect of FDI changes on GDP growth in Malta from 1971 to 2017. Real GDP, trade, and manufacturing are all integrated into order 1, while FDI is stationary according to the unit root and stationarity tests. Given these tests, a statistically significant causal association emerged between FDI and economic growth. Ciobanu, Sova, and Popa (2020) examined the impact of FDI on economic growth. They employed panel data from annual statistics from Eurostat for the CEE nations of Bulgaria, Czech Republic, Estonia, Hungary, Lithuania, Latvia, Poland, Romania, Slovenia, and Slovakia between 2009 and 2018. The panel data regression model of CEE economies shows that FDI inflows are positively correlated with GDP growth.

Loukil (2016) examines the impact of FDI on technological innovation in developing countries. The sample comprises 54 developing countries for the period 1980-2009. The estimation of the panel threshold model shows the presence of nonlinear effects in the relationship between FDI and innovation. The study finds a threshold value of technological development below which FDI has a negative impact on innovation and above which FDI has a significant positive impact on innovation.

Osano and Koine (2016) examined the role of FDI in technology transfer and economic growth in Kenya, focusing on the energy sector in Nairobi for 2001–2014. This study adopted a descriptive and an inferential survey design. The study population comprised 60 senior managers, including directors.
and managers from Kenya Power and Kengen. The questionnaires were used to collect primary data. The study established a relationship between foreign direct investment variables of infrastructure, technology diffusion, trade facilitation, knowledge management, technology transfer, and economic growth.

Seyoum, Wu, and Yang (2015) examined the impact of Chinese outbound direct investment on the productivity of domestic firms. They used survey data from 1033 manufacturing firms operating in Ethiopia in 2011. The results show that foreign firms are more productive, and that their presence has different spillover effects on domestic firms’ productivity. In particular, they find that domestic firms with higher absorptive capacity experience positive spillovers, while those with low absorptive capacity witness negative spillovers. They also find that small firms and non-exporting firms benefit more from spillovers than other types of domestic firms.

Awosusi and Awolusi (2014) study technology transfer, foreign direct, and economic growth in Nigeria. They used time series data from 1970 to 2010. They employ the multivariate co-integration technique developed by Johansen and Juselius (1990) to investigate the long-run equilibrium relationships between international factors and economic growth. The results confirmed the existence of cointegrating vectors in the systems of this country during the study period. The short-term impact of inward FDI, trade, and economic growth on international technology transfer to Nigeria was also tested using the Granger Causality test based on the vector error correction model. The test results revealed a short-run causal effect, running unidirectionally or bidirectionally, among the variables for the country.

Lemma et al. (2014) examined the role of FDI on technology transfer in Ethiopian metal and engineering industries. They surveyed 47 metal and engineering industries in China. The study finds that the technological capability of local industries to adopt, modify, and improve a given technology is very weak, there is an un-collaborative operating environment between foreign and local industries, and the national technology policies are very weak to benefit from FDI. They suggest policies and develop a framework.

Kunle et al. (2014) analyzed the impact of FDI on Nigeria’s economic growth over the period of 1999-2013. The study used secondary data sourced from various publications of the Central Bank of Nigeria, such as the Statistical Bulletin, Annual Reports, and Statement of Accounts. They used the ordinary least squares (OLS) estimation technique to determine the relationship between and the impact of FDI on economic growth. The study finds that economic growth is directly related to FDI inflow of foreign direct investment and is statistically significant at the 5% level.

C. Zhang, Guo, and Wang (2014) investigated the effects of FDI on the Chinese industry by estimating several specifications. He used a large panel of data for 21 manufacturing sectors and 31 regions covering 2005–2010. He constructed a multidimensional index to measure industrial performance. He used total share and per capita industrial output by FDI as independent variables, which seems to be more suitable for capturing the effects of FDI on Chinese industrial capabilities. He suggests that FDI has become a driving force for industrial performance, as the Chinese Industrial Competitiveness (IC) ability to produce, competitively export manufactured goods, enhance low-tech manufacturing, and contribute to interaction with local human capital during the 2005–2010 period. The "transfer of technology and managerial knowledge to the host country is considered to have positive spillover effects on the economy.

Yang, Chen, and Huang (2013) investigated the impact of outward foreign direct investment (OFDI) on the technical efficiency of the OFDI firms. They use firm-level panel data from Taiwan’s manufacturing industry from 1987 to 2000. They used propensity score matching to construct an appropriate group of non-OFDI firms to compare with OFDI firms, and subsequently used a meta-frontier framework to calculate comparable technical efficiencies for both groups of firms. The results reveal that the technical efficiency of Taiwan’s manufacturing firms increased over the entire sample.
period. The results also suggest that technological advances and technical efficiency of Taiwanese manufacturing firms are positively correlated with their OFDI activity.

Bodman and Le (2013) studied the impact of technology embodied in FDI on the total factor productivity (TFP) of FDI-receiving countries, shedding new light on where the sources of research and development (R&D) spillovers lie and directly addressing the important question of whether more FDI leads to a better-trained labour force. Their findings show that countries that have embraced a relatively more open international investment regime have usually grown significantly faster than others that have not. It is suggested that the fact that FDI transmits technological knowledge and contributes to the physical capital stock, openness to direct physical investment, as well as trade and financial flows, provides an important driver of economic growth. It was also found that apart from human capital being necessary for the direct general enhancement of the technological level itself, it is essential for the ability to learn from foreign technological sources.

Solomon and Eka (2013) investigated the relationship between FDI and economic growth in Nigeria. The study covered the period 1981-2009 using annual data from the Central Bank of Nigeria Statistical Bulletin. A growth model using the ordinary least squares method was used to ascertain the relationship between FDI and economic growth in Nigeria. The results of the OLS technique indicated that FDI had a positive but insignificant impact on Nigeria’s economic growth during the study period.

3. Methodology
The study adopted an ex post facto research design. This design is deemed suitable considering the historical nature of the data with a lack of manipulation. The design also guided the nature and sources of data, step-by-step processes used for model specification (subdivided into the model for regression analysis, unit root test, a priori expectation, and description of variables), evaluation of estimates (i.e., the regression coefficients were evaluated in line with the econometric criteria [p<.05]), and test of hypotheses.

3.1. Nature and Sources of Data
The data used for the empirical analyses were secondary in nature. Data were collected from the World Bank (World Development Indicators). The data cover the period (1990-2021).

3.2. Model Specification
3.2.1. Model for the regression analyses
The model is adapted from the work of L. Erdal and Göçer (2015); in line with the objectives of the study the following regression models are specified:
That is:

\[ \text{GDPGR} = f(\text{FDNI}, \text{DEGO}, \text{INFL}) \]  

\[ \text{GDPGR} = \alpha_0 + \alpha_1 \text{FDNI} + \alpha_2 \text{DEGO} + \alpha_3 \text{INFL} + \mu_0 \]  

Where,
GDPGR is the GDP growth (annual %)
FDNI is the Foreign direct investment, net inflows (% of GDP)
DEGO is the Degree of Economic Openness
INFL is the Inflation rate

3.1.2. Unit root test
In probability theory and statistics, a unit root is a feature of stochastic processes (randomly determined) that can cause problems in statistical inference involving time-series models. Tests of causality assume that time-series data are stationary. Therefore, a test of stationarity precedes a test of causality. This study conducted an Augmented Dickey-Fuller (ADF) test for unit roots. The ADF test provided the
convenience to produce an unbiased estimate since it has a pure white noise error term ($\epsilon_t$) which is achieved by adding the lagged difference of the regressand. This is an obvious advantage of the ADF test compared to the DF test.

3.1.3. **Description of Variables**
The variables included in the model were the FDNI, DEGO, and INFL. There are three categories of variables in the specified models: dependent, independent, and control. This is explained as follows.

Table 2. Operationalisation of the model variables

**3.3. Estimation Technique and Procedure**
Multiple regression analysis provides a means of assessing the degree and character of the relationship between the independent variables and the dependent variable, and the regression coefficients indicate the relative importance of each of the independent variables in the prediction of the dependent variable (Sekaran & Bougie, 2013). The study adopted the ordinary least squares (OLS) technique for various analyses. The choice of this method is influenced by the optimal properties of OLS, which enables estimates to have minimum variance (Gujarati & Porter, 2009; Koutsoyiannis, 1977).

3.3.1. **Statistical Criterion**
The square of the correlation $R^2$ and adjusted $R^2$ were used to evaluate the extent to which the explanatory variables were responsible for the changes in the dependent variable of the relationship. The standard error was used to evaluate the statistical significance of the estimates. A very low standard
error was preferred. Durbin-Watson d statistics test the validity of the assumption of non-autocorrelation disturbances. The test of the research hypotheses postulated in this study was based on the significance of the parameter estimates. Considering the \textit{a priori} criteria stated in this study, the conventional \(t\) and \(f\) values evaluated the individual and collective significance of the variables in the model at the 5% level of significance. The null is rejected when the computed \(t\) or \(f\) value is greater than the critical \(t\) or \(f\) value.

3.3.2. \textit{Apriori Expectation}

FDNI > 0 (+)

DEGO > 0 (+)

INFL < 0 (-)

4. Results and discussions

4.1. Descriptive Statistics

In this section, we examine the descriptive statistics for both model variables of interest. Each variable was examined based on mean and median values. The statistical makeup of the time series under investigation was revealed by the minimum, maximum, and standard deviations. The Jarque-Bera-Bera statistic shows how the series is distributed, and evaluates the assertion that the data are normally distributed. Table 2 displays the descriptive statistics for the study, while Figures 1 and 2 show the time-series plot. Skewness and kurtosis were computed for all variables. In step two, the stationarity properties of the data are ascertained to ensure that the variables are devoid of stationarity defects, which may affect the output of the regression equation.

The mean (median) of GDPGR of the studied years 1990-2021 was 4.320114 (4.430627). The maximum value of GDPGR was approximately 15.32916, whereas the minimum value was -2.035119. The J-B statistic value was 1.120671, with a probability value of 0.571, indicating that the variable is normally distributed.
The mean FDNI of the studied years was 1.628123 and the median value was 1.487050. A low standard deviation indicates that the data are clustered around the mean. The maximum value of the FDNI was approximately 5.790847, while the minimum was approximately 0.183822. The J-B statistic value was 38.759, with a probability value of 0.000, indicating that the variable was not normally distributed.

The mean DEGO of the studied years was 36.16016 and the median value was 36.54016. A low standard deviation indicates that the data are clustered around the mean. The maximum value of DEGO was approximately 53.27796, whereas the minimum was approximately 16.35219. The J-B statistic value was 0.513, with a probability value of 0.773, indicating that the variable is normally distributed.
mean INFL of the study years was 16.77771, with a median value of 10.17976. A low standard deviation indicates that the data are clustered around the mean. The maximum INFL value was approximately 75.40165, while the minimum was approximately 0.686099. The J-B statistic value was 49.725, with a probability value of 0.000, indicating that the variable was not normally distributed.

4.2. Correlation Matrix

To examine the association among the variables, we employed the Pearson correlation coefficient (correlation matrix); the results are presented in the table below.

Table 4. Correlation analysis of the model variables for the test of the hypothesis

<table>
<thead>
<tr>

Source: E-Views 11

In the table above, the GDPGR positively correlates with FDNI (0.598877), DEGO (0.443217), and INFL (0.301127). FDNI was positively correlated with DEGO (0.464183) and INFL (0.198561). DEGO, DEGO positively correlated with INFL (0.21507).

4.4. Diagnostic Tests

4.4.1. Unit Root Test

The data were subjected to unit root tests using Augmented Dickey-Fuller (ADF). This was carried out using three criteria: intercept, intercept, trend, and none. Our result, as depicted in Table 4, reveals that the data have no stationarity defect that may cast a dent in the statistical reliability of the regression output.

Null Hypothesis (H₀) : The variable X has a unit root
Alternate Hypothesis (H₁) : The variable X has no unit root

Note: *, **, and *** denote significance at the 10 %, 5 %, and 1% levels, respectively, whereas 1(0) and 1(1) denote the integration order at the level and the first difference, respectively. The outcomes shown in Table 4 support the stationarity of the data at the first difference (Nwosu et al., 2023).

4.5. Test of Hypotheses

To test the hypotheses stepwise regression was estimated since correlation analysis does not imply a cause-effect relationship (Alvindra, Hutagalung, & Sutiyoso, 2023). The model shows a good fit; thus, residual diagnostics were also conducted to look for serial correlation, heteroskedasticity, and distributional normality. For any model to have meaningful predictive value, the absence of correlation, presence of homoscedasticity, and normal distribution of residuals are necessary prerequisites.

Source: E-Views 11

The F-statistic value of 5.297 and its associated p-value of 0.006 show that the regression model is statistically significant at the 5% level, which means that the regression model is valid and can be used for statistical inference. In the table above, the regression R-squared value of 0.419 and the Adjusted R-squared value of 0.340 show that about 34.02% of the systematic variations in GDPGR were jointly explained by the explanatory variables. The Adjusted R-squared value is often preferred to account for sample-size adjustments.

4.6. Decision Rule
Since the p-value is less than .05, we reject the null hypothesis and accept the alternate hypothesis; thus, there is a significant effect of foreign direct investment net inflow on the GDP growth rate. The signs of the coefficients of the explanatory variables varied. This evidence, therefore, leads to a rejection of the null hypothesis and acceptance of the alternate: “There is a significant effect of foreign direct investment net inflow on the GDP growth rate.” The CVs, that is, DEGO (p=0.3299) and INFL (p=0.3321), had a positive non-significant effect on GDPGR. Egbunike and Oranefo (2023) also find a positive effect of INFL on the ROA of pharmaceutical firms at 75% quantiles.

4.7. Robustness Check
According to studies by Hayakawa and Kurozumi (2008), Kao and Chiang (2001), and others, the dynamic OLS approach entails adding lags and leads to a cointegrating regression to make the resulting cointegrating equation error term orthogonal to the full history of stochastic regressor innovations.
Using DOLS, the variable FDNI also showed a positive coefficient, DEGO had a positive coefficient, and INFL had a negative coefficient. The coefficients were only significant for the latter two (since the p-value was less than .05).

4.8. Discussion of Findings

The study finds a significant positive effect of foreign direct investment net inflow on the GDP growth rate. Shinwari et al. (2023) using Afghanistan’s FDI and economic growth data analysed using the ARDL technique showed that FDI positively affected economic growth. The results are consistent with Nairobi, Ambya, Afif, and Pratikno (2022), who use data from ASEAN-5 countries and find that FDI is positively associated with GDPPC.

Also, Liu, Luo, Qiu, and Zhang (2014), discovered that FDI supported growth by improving the accumulation of physical and human capital, it also had unfavourable consequences since it led to an interregional growth gap. Consistent with this, Nwaogu and Ryan (2015) examined the effects of FDI, aid, and remittances on the economic growth of SSA countries, and discovered that FDI was positive and significant exclusively for SSA nations. Magazzino and Mele (2022) examined the association between FDI and economic growth in Malta from 1971 to 2017, confirming this. Using data from the CEE countries, Ciobanu et al. (2020) showed that FDI inflows are highly positively correlated with GDP growth.

By contrast, using a sample of countries in South Asia and Southeast Asia, Rao et al. (2023) find that FA is negatively associated with FDI and economic growth, whereas FDI is positively associated with the economic growth proxy. Gunby, Jin, and Reed (2017), used meta-analysis to determine if productivity spillovers from FDI at the firm had been significant enough to have an impact on China’s overall growth. This study discovered a negligible impact of FDI on economic growth in China. However, Rajan and Subramanian (2008) find little evidence of a positive (or negative) relationship between FDI and economic growth using cross-sectional and panel data. Indeed, Sahoo and Sethi (2017) found that FDI has no favorable impact on India’s economic growth.

5. Conclusion

The study concludes that there inflows have a specific and significant effect on the GDP growth rate. This study employed push and pull factors to describe the factors that affect foreign direct investment net
inflows. Therefore, this study recommends the following for policymakers and stock market regulators to develop robust policies that enhance the GDP growth rate.

This encourages authorities, especially in developing countries, to implement policies aimed at increasing economic growth, stock market development, and trade degree openness to attract more foreign portfolio investment. Further, the degree of economic openness (DEGO) is crucial for countries in SSA to boost domestic investment and turns out to be positive in all empirical estimations insofar as it is positively associated with GDPGR. The emergence of FDI net inflows aids the host nation’s development on several fronts, including the adoption of cutting-edge technologies and managerial concepts involving human capital and the flow of beneficial foreign capital.
